                                        SUBTTL  2901 Tests

                                ;#*********************************************************************
                                ; These tests do arithmetic and logical operations using the 2901's
                                ; exclusively, not using the D inputs or relying on any logic to gate
                                ; data onto the MBus and then into the 2901's.  These tests move data
                                ; around in the internal registers of the 2901's to accomplish their
                                ; testing, and data is gated into the EBUF for verification.
                                ;#*********************************************************************

                                ;#*********************************************************************
                                ;* Test 1 - 2901 0's Test
                                ;
                                ; Description:  Verify that xx AND 0's ==> 0's. The source inputs
                                ;               specified  are  any  in  the  form xx and 0.  The
                                ;               destinations are any specifying that the Y output
                                ;               is put on the MBUS which is then  gated  into the
                                ;               EBUF and  verified.  The  function  used  is  AND
                                ;               except  for  one  combination using NAND which is
                                ;               equivalent.
                                ;

                                                SUBTTL  2901 Boolean Tests (Direct Input/0)

                                        ;#**********************************************************************
                                        ; These tests do the most basic testing of the 2901's.  Data is gated
                                        ; from the D inputs into the ALU.  An operation is then performed on the
                                        ; data and zero, and the result put on the Y outputs.  If these tests
                                        ; work there is some confidence in the data path of the direct input and
                                        ; output.  Further tests can then test the 16 RAM locations and ALU and
                                        ; destination control.  And further tests can then verify the Q register
                                        ; and data shifting.
                                        ;#**********************************************************************

        SUBTTL  2901 ALU Function Tests

;#**********************************************************************
; This section consists of more  complete ALU testing using all
; combinations of  source  operands and doing all ALU functions
; on them.  For the logical operations  tests, the state of the
; carry in bit should have no effect - it is randomly sprinkled
; through the tests.
;#**********************************************************************

;#**********************************************************************
;* Test 16 - 2901 OR Test
;
; Description:  Verify that 0's OR 0's ==> 0's
;               Verify that 0's OR 1's ==> 1's
;               Verify that 1's OR 1's ==> 1's
;
; Procedure:    Clear Port
;               Load microcode
;
;               Set RAR to 0
;               Execute 34. JMAP's
;               Read EBUF (Contains contents of Reg 0)
;               Verify data is correct (0's)
;
;               Set RAR to 42
;               Execute JMAP
;               Read EBUF (Contains contents of Q-Reg)
;               Verify data is correct (0's)
;
;               Set RAR to 43
;               Execute 17. JMAP's
;               Read EBUF (Contains contents of Reg 0)
;               Verify data is correct (1's)
;
;               Set RAR to 64
;               Execute JMAP
;               Read EBUF (Contains contents of Q-Reg)
;               Verify data is correct (1's)
;
;               Set RAR to 65
;               Execute 12. JMAP's
;               Read EBUF (Contains contents of Reg 0)
;               Verify data is correct (1's)
;
;               Set RAR to 101
;               Execute JMAP
;               Read EBUF (Contains contents of Q-Reg)
;               Verify data is correct (1's)
;
; Failure:      ---
;#**********************************************************************
